## **UDP: User Datagram Protocol**

- "no frills," "bare bones"
   Internet transport protocol
- "best effort" service, UDP segments may be:
  - lost
  - delivered out-of-order to app

### connectionless:

- no handshaking between UDP sender, receiver
- each UDP segment handled independently of others

### Why is there a UDP?

- no connection establishment (which can add RTT delay)
- simple: no connection state at sender, receiver
- small header size
- no congestion control
  - UDP can blast away as fast as desired!
  - can function in the face of congestion

### **UDP: User Datagram Protocol**

- UDP use:
  - streaming multimedia apps (loss tolerant, rate sensitive)
  - DNS
  - SNMP
  - HTTP/3
- if reliable transfer needed over UDP (e.g., HTTP/3):
  - add needed reliability at application layer
  - acc congestion control at application layer

### **UDP: User Datagram Protocol** [RFC 768]

INTERNET STANDARD

**RFC 768** 

J. Postel ISI 28 August 1980

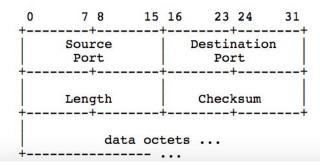

#### User Datagram Protocol

#### Introduction

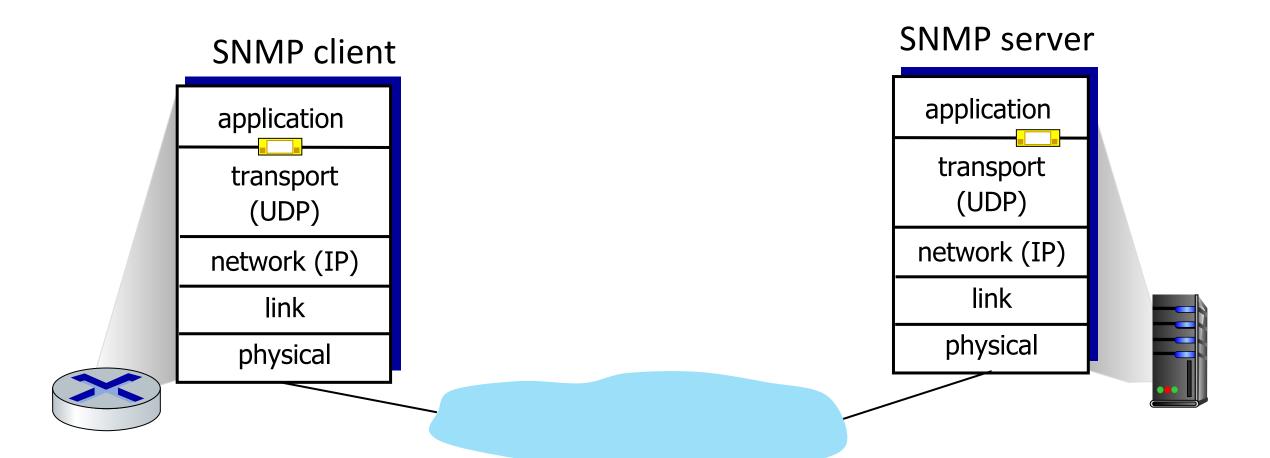

This User Datagram Protocol (UDP) is defined to make available a datagram mode of packet-switched computer communication in the environment of an interconnected set of computer networks. This protocol assumes that the Internet Protocol (IP)  $[\underline{1}]$  is used as the underlying protocol.

This protocol provides a procedure for application programs to send messages to other programs with a minimum of protocol mechanism. The protocol is transaction oriented, and delivery and duplicate protection are not guaranteed. Applications requiring ordered reliable delivery of streams of data should use the Transmission Control Protocol (TCP) [2].

#### Format

# **UDP: Transport Layer Actions**

### **UDP: Transport Layer Actions**

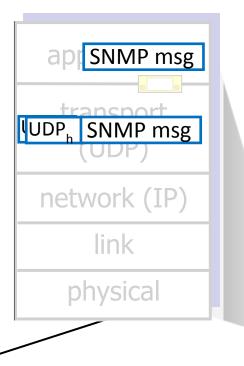

#### SNMP client

application
transport
(UDP)
network (IP)
link
physical

#### **UDP** sender actions:

- is passed an application-layer message
- determines UDP segment header fields values
- creates UDP segment
- passes segment to IP

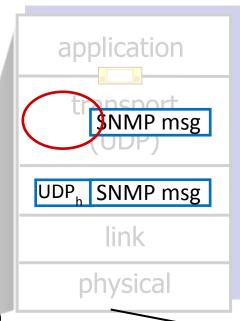

#### **SNMP** server

### **UDP: Transport Layer Actions**

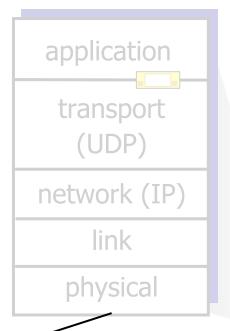

#### SNMP client

#### **UDP** receiver actions:

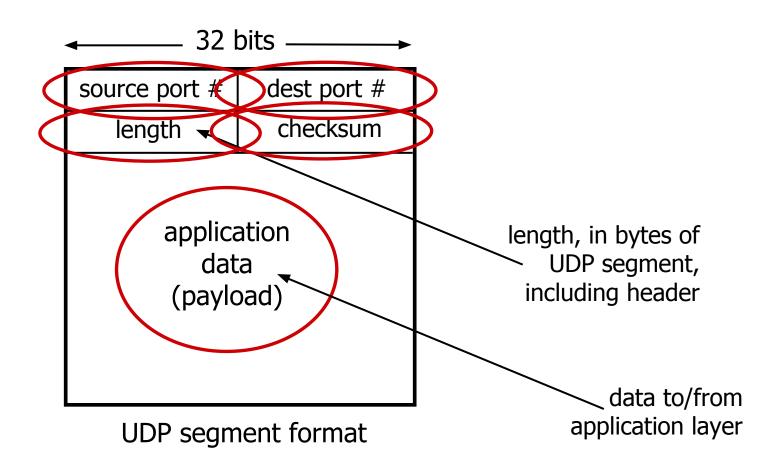

- receives segment from IP
- checks UDP checksum header value
- extracts application-layer message
- demultiplexes message up to application via socket

#### **SNMP** server

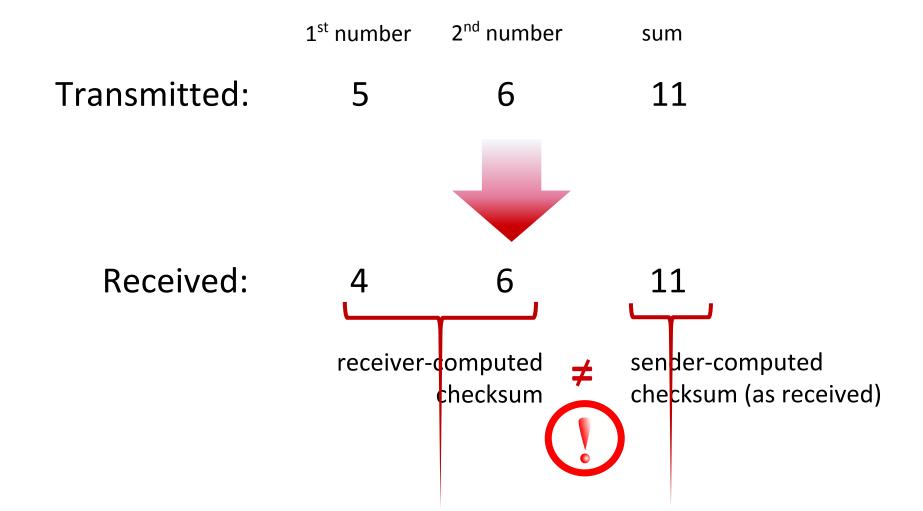

# **UDP** segment header

### **UDP** checksum

*Goal:* detect errors (*i.e.*, flipped bits) in transmitted segment

### **UDP** checksum

*Goal:* detect errors (i.e., flipped bits) in transmitted segment

### sender:

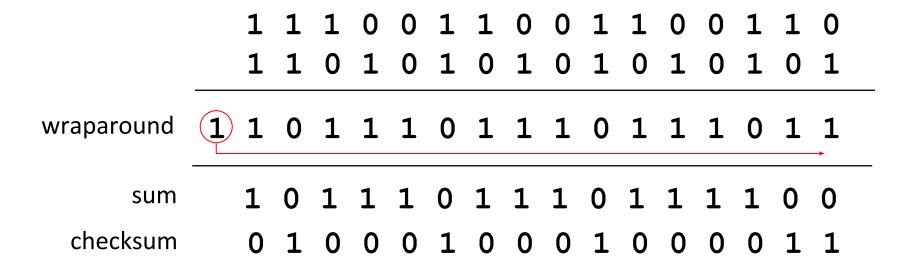

- treat contents of UDP segment (including UDP header fields and IP addresses) as sequence of 16-bit integers
- checksum: addition (one's complement sum) of segment content
- checksum value put into UDP checksum field

### receiver:

- compute checksum of received segment
- check if computed checksum equals checksum field value:
  - Not equal error detected
  - Equal no error detected. But maybe errors nonetheless? More later ....

## Internet checksum: an example

example: add two 16-bit integers

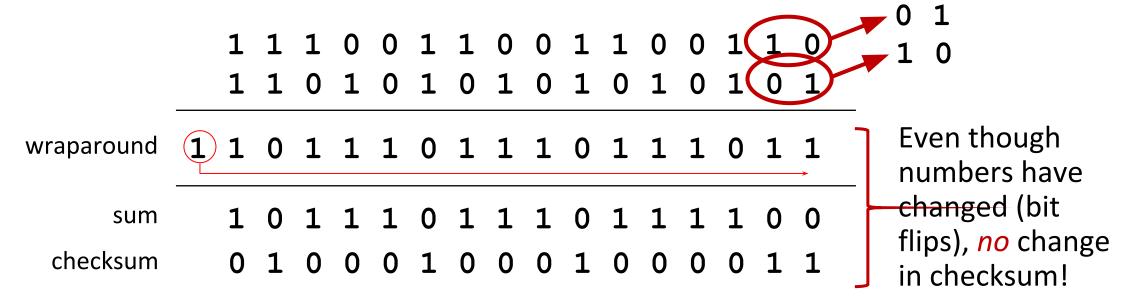

*Note:* when adding numbers, a carryout from the most significant bit needs to be added to the result

<sup>\*</sup> Check out the online interactive exercises for more examples: http://gaia.cs.umass.edu/kurose\_ross/interactive/

## Internet checksum: weak protection!

example: add two 16-bit integers

# **Summary: UDP**

- "no frills" protocol:
  - segments may be lost, delivered out of order
  - best effort service: "send and hope for the best"
- UDP has its plusses:
  - no setup/handshaking needed (no RTT incurred)
  - can function when network service is compromised
  - helps with reliability (checksum)
- build additional functionality on top of UDP in application layer (e.g., HTTP/3)
